We investigate classification and detection of multipartite entanglement in a very general setting. The $k$-separability of mixed $n$-partite ($n \geq 3$) quantum states is mainly discussed in this paper. We obtain practical $k$-separability criteria which identify $k$-nonseparable mixed multipartite states in arbitrary dimensional quantum systems, characterize the different classes of multipartite entanglement and detect multipartite entanglement ($k$-nonseparable $n$-partite quantum states) which have previously not been identified. Our criteria can be used to distinguish the different classes of multipartite entanglement and can detect many important multipartite entanglement states such as GHZ state, W state, and anti-W state efficiently. They can be used for detecting not only genuine $n$-partite entangled mixed states ($k = 2$) but also $k$-nonseparable mixed multipartite states (not $k$-separable states) ($k = 3, 4, \ldots, n$). No optimization or eigenvalue evaluation is needed, our criteria can be evaluated by simple computations involving components of the density matrix and can be implemented in today’s experiments. That is, our criteria can be used for experimental detection of multipartite entanglement.

I. INTRODUCTION

Quantum entanglement is a new quantum resource for tasks that cannot be performed by means of classical resources, and has widely been applied to quantum communication [1–8] and quantum computation [9, 10]. So, it owns theoretical and practical value to study the separability of quantum states.

There is a substantial bulk of work for bipartite systems, in particular for the case of qubits. Many well-known (necessary) separability criteria have been proposed to distinguish separable from entangled states, such as the Bell inequalities [11], positive partial transposition (PPT) [12] (which is also sufficient for $2 \otimes 2$ or $2 \otimes 3$ systems [13]), reduction [14, 15], range [16], majority [17], realignment [18–20], generalized realignment [21], and covariance matrix [22, 23] etc.. Covariance matrix criterion [22, 23] is a strong entanglement criterion, which can detect states where the PPT criterion fails and which is at the same time necessary and sufficient for two qubits. All these criteria above work very well in many cases, but are far from perfect [24]. The success in the bipartite case for qubits asked for extensions to the multipartite and high dimensional systems, but the situation proved to be far more complicated: Different classes of entanglement occur, which are inequivalent not only under deterministic local operations and classical communication, but even under their stochastic analog [25, 26]. Owing to the complicated structure of multipartite entangled states, it is difficult to decide to which class a given multipartite state belongs.

As genuine multipartite entanglement and $k$-nonseparability are being more and more understood, tools for their detection are beginning to be developed [27–33]. Separability criteria for two types of multipartite qubit states were presented in Ref.[28]. Gittsovich et al. [29] derived a multipartite covariance matrix criterion detecting multiparticle state that is not fully separable. This criterion allows detection of bound entangled states which are not detected by other commonly used criteria. However, some strongly entangled pure states such as the Greenberger-Horne-Zeilinger (GHZ) states are not detected by the multipartite covariance matrix criterion [29]. A necessary criterion for $k$-separability was derived in Ref.[31]. In Refs.[32, 33], we obtained separability criteria to detect genuinely entangled and nonseparable $n$-partite mixed quantum states in arbitrary dimensional systems.

$k$-separability provides a fine graduation of states according to their degrees of separability [34]. The detection of genuine $k$-nonseparability in mixed states is essential. In this paper, we aim to present powerful criteria to identify $k$-nonseparable $n$-partite mixed states in arbitrary dimensional quantum systems. These criteria have the following advantages: First, they can be used to distinguish the different classes of multipartite entanglement. Second, they can detect many important multipartite entanglement states such as GHZ state, W state, and anti-W state efficiently.

*Electronic address: gaoting@hebtu.edu.cn
Third, they allow us to detect some classes of $k$-nonseparable $n$-partite quantum states that can not be detected by all previously studied criteria. Last but not least, these criteria are experimentally feasible without state tomography, at the same time, they are easy computable, no optimization process is needed.

II. DEFINITIONS

An $n$-partite system is described by a Hilbert space $\mathcal{H}$ that decomposes into a direct product of $n$ subspaces $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \cdots \otimes \mathcal{H}_n$, where the dimension of the Hilbert space $\mathcal{H}_i$ will be denoted by $d_i$. An $n$-partite pure state $|\psi\rangle \in \mathcal{H}$ is called $k$-separable [34–36] if there is a $k$-partition $j_1^1 \cdots j_{m_1}^1 | j_2^2 \cdots j_{m_2}^2 \cdots | j_k^k \cdots j_{m_k}^k$, such that

$$|\psi\rangle = |\psi_1\rangle_{j_1^1 \cdots j_{m_1}^1} |\psi_2\rangle_{j_2^2 \cdots j_{m_2}^2} \cdots |\psi_k\rangle_{j_k^k \cdots j_{m_k}^k},$$

(1)

where $|\psi_m\rangle_{j_i^i}$ is the state of particles $j_i^1, j_i^2, \cdots, j_i^{m_i}$, and $\bigcup_{i=1}^{k} \{j_i^1, j_i^2, \cdots, j_i^{m_i}\} = \{1, 2, \cdots, n\}$. That is, an $n$-partite pure state is $k$-separable, iff it can be written as a product of $k$ substates. An $n$-partite mixed state $\rho$ is called $k$-separable if it can be written as a convex combination of $k$-separable pure states

$$\rho = \sum_m p_m |\psi_m\rangle \langle \psi_m|,$$

(2)

where $|\psi_m\rangle$ might be $k$-separable under different partitions. That is, an $n$-partite mixed state $\rho$ is $k$-separable, iff it has a decomposition into $k$-separable pure states. The individual pure states composing a $k$-separable mixed state may be $k$-separable under different partitions. $k$-separability provides a fine graduation of $n$-partite quantum states according to their different degrees of separability [34]. In particular, an $n$-partite state is called fully separable, iff it is $n$-separable. It is called genuinely $n$-partite entangled, iff it is not bi-separable (2-separable). In general, $k$-separable mixed states are not separable with regard to any specific partition, which makes $k$-separability rather difficult to detect.

Note that whenever a state is $k$-separable, it is automatically also $k'$-separable for all $1 < k' < k$. For five qubit state $|\psi\rangle = 1\over\sqrt{2}(|00000\rangle + |01010\rangle + |10100\rangle + |11110\rangle)_{12345}$, it is 3-separable since it can be rewritten as $|\psi\rangle = 1\over\sqrt{2}(|00\rangle_{12} + |11\rangle_{12})_{345}$ under 3-partition $12|345$, it is also 2-separable (bi-separable) since there is a 2-partition $13|245$ such that $|\psi\rangle = 1\over\sqrt{2}(|00\rangle_{13} + |11\rangle_{13})_{245}$, but it is not 4-separable (4-nonseparable) since it can not be expressed as a product of 4 substates under any 4-partition.

There exist bi-separable states that are entangled with respect to a fixed bipartition. The following states, being mixtures of states that are separable with respect to some bipartition, still carry some entanglement, i.e. neither it can be written as a mixture of separable states with respect to some fixed bipartition nor as a mixture of fully separable states. Three qubit states $|\psi_1\rangle = 1\over\sqrt{2}(|00\rangle + |11\rangle)_{12}|0\rangle_3$, $|\psi_2\rangle = 1\over\sqrt{2}(|00\rangle + |11\rangle)_{13}|0\rangle_2$, and $|\psi_3\rangle = 1\over\sqrt{2}(|00\rangle + |11\rangle)_{12}|0\rangle_3$ are 2-separable under 2-partition $1|23$, $13|2$, and $12|3$, respectively. Their convex combinations $\rho = p_1|\psi_1\rangle \langle \psi_1| + p_2|\psi_2\rangle \langle \psi_2| + p_3|\psi_3\rangle \langle \psi_3| \ (p_i > 0, \sum p_i = 1)$ are mixtures of bi-separable states with respect to different partitions, and therefore bi-separable. However, as can be easily checked, $\rho$ is entangled with respect to each fixed bipartition, that is, it can not be written as a convex combination of bi-separable states with respect to a fixed bipartition.

Before we formulate our separability criteria, an introduction of notations that will be involved in the subsequent sections of our article is necessary. Let $P_i$ be the operator swapping the two copies of $\mathcal{H}_i$ in $\mathcal{H}^{\otimes 2} = (\mathcal{H}_1 \otimes \mathcal{H}_2 \cdots \otimes \mathcal{H}_n)^{\otimes 2}$, i.e. it performs a permutation on $\mathcal{H}^{\otimes 2}$ and leaves all other subsystems unchanged $P_i|x_1 \cdots x_{i-1}x_{i+1} \cdots x_n\rangle\langle y_1 \cdots y_{i-1}y_{i+1} \cdots y_n| = |x_1 \cdots x_{i-1}y_ix_{i+1} \cdots x_n\rangle\langle y_1 \cdots y_{i-1}x_iy_{i+1} \cdots y_n|$, while $P_i$ is the adjoint or Hermitian conjugate of the operator $P_i$. $P_{tot}$ denotes the operator that performs a simultaneous local permutation on all subsystems in $\mathcal{H}^{\otimes 2}$, that is $P_{tot} = P_1 \circ P_2 \circ \cdots \circ P_n$. A simple example would be $P_{tot}|x_1x_2 \cdots x_n\rangle\langle y_1y_2 \cdots y_n| = |y_1y_2 \cdots y_n\rangle\langle x_1x_2 \cdots x_n|$.

III. THE $k$-SEPARABILITY CRITERIA FOR $n$-PARTITE QUANTUM STATES

Theorem 1 Suppose that $\rho$ is an $n$-partite density matrix acting on Hilbert space $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \cdots \otimes \mathcal{H}_n$ with dim $\mathcal{H}_i = d_i \geq 2$. Let $|\Phi_i\rangle = |\phi_i\rangle |\phi_i\rangle$, where $|\phi_i\rangle = |x_1x_2 \cdots x_{i-1}x_{i+1} \cdots x_n\rangle$ are fully separable states of $\mathcal{H}_i$. If $\rho$ is $k$-separable, then

$$\sum_{i \neq j} \sqrt{\langle \Phi_{ij}\rangle \rho^{\otimes 2} P_{tot} |\Phi_{ij}\rangle} \leq \sum_{i \neq j} \sqrt{\langle \Phi_{ij}\rangle \rho^{\otimes 2} P_i |\Phi_{ij}\rangle} + (n-k) \sum_i \sqrt{\langle \Phi_{ii}\rangle \rho^{\otimes 2} P_i |\Phi_{ii}\rangle}. $$

(3)
Here $P_{tot}$ denotes the operator that performs a simultaneous local permutation on all subsystems in $\mathcal{H}^{\otimes 2}$, while $P_i$ just performs a permutation on $\mathcal{H}_i^{\otimes 2}$ and leaves all other subsystems unchanged. Of course, $\rho$ is a $k$-nonseparable $n$-partite state if it violates the above inequality (3).

**Proof.** The proof is similar to that of Theorem 1 in Ref. [32]. To establish the validity of inequality (3) for all $k$-separable states $\rho$, let us first verify that this is true for any $k$-separable pure state $\rho$.

Suppose that $\rho = |\psi\rangle\langle\psi|$ is a $k$-separable pure state under a partition of $\{1, 2, \cdots, n\}$ into $k$ pairwise disjoint subsets: $\{1, 2, \cdots, n\} = \bigcup_{l=1}^{k} A_l$ with $A_l = \{j_{1}^l, j_{2}^l, \cdots, j_{n_{l}}^l\}$, and

$$|\psi\rangle = |\psi_{1}\rangle_{j_{1}^1} \cdots |\psi_{k}\rangle_{j_{1}^k}.$$  \hfill (4)

By calculation, one has

$$\sqrt{\langle \Phi_{ij} | \rho^{\otimes 2} P_{tot} | \Phi_{ij} \rangle} \leq \sqrt{\langle \Phi_{ii} | P_i^{\dagger} \rho^{\otimes 2} P_i | \Phi_{ii} \rangle}$$ \hfill (5)

in case of $i,j$ in same part, and

$$\sqrt{\langle \Phi_{ij} | \rho^{\otimes 2} P_{tot} | \Phi_{ij} \rangle} \leq \sqrt{\langle \Phi_{ij} | P_i^{\dagger} \rho^{\otimes 2} P_i | \Phi_{ij} \rangle}$$ \hfill (6)

in case of $i,j$ in different parts ( $i \in A_{l}, j \in A_{l'}$ with $l \neq l'$). Here $|\phi\rangle = \bigotimes_{i=1}^{n} |\phi_{i}\rangle = |x_{1}x_{2} \cdots x_{n}\rangle$ and $|\phi_{ij}\rangle = |x_{1} \cdots x_{i-1} x_{i+1} \cdots x_{j-1} x_{j+1} \cdots x_{n}\rangle$ are fully separable states of Hilbert space $\mathcal{H}$. Combining (5) and (6) gives that

$$\sum_{i \neq j} \sqrt{\langle \Phi_{ij} | \rho^{\otimes 2} P_{tot} | \Phi_{ij} \rangle} = \sum_{i \in A_{l}, j \in A_{l'}, l \neq l'} \sqrt{\langle \Phi_{ij} | \rho^{\otimes 2} P_{tot} | \Phi_{ij} \rangle} + \sum_{i,j \in A_{l}, i \neq j, l \in \{1, 2, \cdots, k\}} \sqrt{\langle \Phi_{ij} | \rho^{\otimes 2} P_{tot} | \Phi_{ij} \rangle} \leq \sum_{i \in A_{l}, j \in A_{l'}, l \neq l'} \sqrt{\langle \Phi_{ij} | P_i^{\dagger} \rho^{\otimes 2} P_i | \Phi_{ij} \rangle} + \sum_{i,j \in A_{l}, i \neq j, l \in \{1, 2, \cdots, k\}} \left( \sqrt{\langle \Phi_{ii} | P_i^{\dagger} \rho^{\otimes 2} P_i | \Phi_{ii} \rangle} + \sqrt{\langle \Phi_{jj} | P_j^{\dagger} \rho^{\otimes 2} P_j | \Phi_{jj} \rangle} \right)$$ \hfill (7)

Thus, inequality (3) is satisfied by all $k$-separable $n$-partite pure states.

It remains to show that inequality (3) holds if $\rho$ is a $k$-separable $n$-partite mixed state. Indeed, the generalization of inequality (3) to mixed states is a direct consequence of the convexity of its left hand side and the concavity of its right hand side, which we can see in the following.

Suppose that

$$\rho = \sum_{m} p_{m} \rho_{m} = \sum_{m} p_{m} |\psi_{m}\rangle \langle \psi_{m}| \hfill (8)$$

is a $k$-separable $n$-partite mixed state, where $\rho_{m} = |\psi_{m}\rangle \langle \psi_{m}|$ is $k$-separable. Then, by Cauchy-Schwarz inequality
\[(\sum_{k=1}^{m} x_k y_k)^2 \leq (\sum_{k=1}^{m} x_k^2)(\sum_{k=1}^{m} y_k^2),\]

we have

\[
\sum_{i \neq j} \sqrt{\langle \Phi_{ij} | \rho^\otimes 2 | \Phi_{ij} \rangle} \leq \sum_{i \neq j} \sqrt{\langle \Phi_{ij} | P^\otimes 2 \rho^\otimes 2 | \Phi_{ij} \rangle} + (n-k) \sum_{i} \sqrt{\langle \Phi_{ii} | P^\otimes 2 \rho^\otimes 2 | \Phi_{ii} \rangle} - (n-k) \sum_{i} \langle \Phi_{ii} | P^\otimes 2 \rho^\otimes 2 | \Phi_{ii} \rangle,
\]

as desired. This completes the proof.

The special case of above Theorem 1 is:

**Corollary** Let \( \rho \) be an \( n \)-partite density matrix acting on Hilbert space \( \mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \cdots \otimes \mathcal{H}_n \), and \( |\Phi_{ij}\rangle = |\phi_i\rangle |\phi_j\rangle \) with \( |\phi_i\rangle = |x \cdots y i z \cdots x \rangle \in \mathcal{H}_i \), where the local state of \( \mathcal{H}_l \) is \( |x\rangle \) for \( l \neq i \) and \( |y\rangle \) for \( l = i \). Then

\[
\sum_{i \neq j} \sqrt{\langle \Phi_{ij} | \rho^\otimes 2 | \Phi_{ij} \rangle} \leq \sum_{i \neq j} \sqrt{\langle \Phi_{ij} | P^\otimes 2 \rho^\otimes 2 | \Phi_{ij} \rangle} + (n-k) \sum_{i} \sqrt{\langle \Phi_{ii} | P^\otimes 2 \rho^\otimes 2 | \Phi_{ii} \rangle}.
\]

Here \( P_{tot} \) denotes the operator that performs a simultaneous local permutation on all subsystems in \( \mathcal{H}^\otimes 2 \), while \( P_i \) just forms a permutation on \( \mathcal{H}_i \) and leaves all other subsystems unchanged. If an \( n \)-partite state \( \rho \) does not satisfy the above inequality \((11)\), then \( \rho \) is not \( k \)-separable \((k\)-nonseparable\).

**Theorem 2.** Every fully separable \( n \)-partite state \( \rho \) satisfies

\[
\sqrt{\langle \Phi_{ij} | \rho^\otimes 2 | \Phi_{ij} \rangle} \leq \sqrt{\langle \Phi_{ij} | P^\otimes 2 \rho^\otimes 2 | \Phi_{ij} \rangle}
\]

for fully separable states defined as \( |\Phi_{ij}\rangle = |\phi_i\rangle |\phi_j\rangle \), with \( |\phi_i\rangle = |x_1 \cdots x_{i-1} x_i x_{i+1} \cdots x_n \rangle \in \mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \cdots \otimes \mathcal{H}_n \), where the \( i \)-th local state is \( |x_i\rangle \) and the others are \( |x_k\rangle \) \((k \neq i)\). These are \( \frac{1}{2} n(n-1) \) inequalities, and violation of any one of them implies nonseparability.

**Proof.** Note that the left-hand side of inequality \((11)\) minus the right-hand side of \((11)\) is a convex function of the matrix \( \rho \) entries (since the left-hand side is convex and the right-hand side is concave). Consequently, it suffices to prove the validity for fully separable pure states, and the validity for mixed states is guaranteed.

Suppose that \( \rho \) is a fully separable \( n \)-partite pure state, then one has

\[
\sqrt{\langle \Phi_{ij} | \rho^\otimes 2 | \Phi_{ij} \rangle} = \langle \phi_i | \rho | \phi_j \rangle,
\]

and

\[
\sqrt{\langle \Phi_{ij} | P^\otimes 2 \rho^\otimes 2 | \Phi_{ij} \rangle} = \langle \phi_i | \rho | \phi_i \rangle \langle \phi_j | \rho | \phi_j \rangle = \langle \phi_i | \rho | \phi_j \rangle |\phi_i \rangle |\phi_j \rangle.
\]

Here \( |\phi \rangle = \otimes_{i=1}^{n} |x_i \rangle = |x_1 x_2 \cdots x_n \rangle \) and \( |\phi_{ij} \rangle = |x_1 \cdots x_{i-1} x_i x_{i+1} \cdots x_j x_{j+1} \cdots x_n \rangle \) are fully separable states of Hilbert space \( \mathcal{H} \). The combination of above two equalities gives that \((11)\) holds with equality if \( \rho \) is a fully separable \( n \)-partite pure state.

Our \( k \)-separability criteria can be used to distinguish the different classes of multipartite entanglement and can detect many important multipartite entanglement states such as GHZ state, W state, and anti W state efficiently. They can be used for detecting not only genuine \( n \)-partite entangled mixed states \((k = 2)\) but also \( k \)-nonseparable mixed multipartite states \((k \)-nonseparable\) \((k \geq 3)\). Moreover, it indeed detects \( k \)-nonseparable mixed multipartite states \([k \)-qubit states such as W state mixed with white noise, the mixture of the identity matrix, the W state and the anti-W state, and the mixture of the GHZ state, the W state and the identity matrix] which beyond all previously studied criteria. Theorem 1 in Ref. [32] is the special case of our Corollary above when \( k = 2 \) and can only be used to identify genuine \( n \)-partite entangled mixed states \((k = 2)\).
IV. EXAMPLES

In this section, we illustrate our main result with some explicit examples. It should be pointed out that our criteria are suitable for any $n$-partite states. For simplicity, we give the following examples to show the detecting ability of our criteria.

Example 1 Consider the family of $n$-qubit states

$$\rho^{(G-W_n)} = \alpha |GHZ_n\rangle\langle GHZ_n| + \beta |W_n\rangle\langle W_n| + \frac{1 - \alpha - \beta}{2^n} \mathbb{I},$$

the mixture of the GHZ state and the W state, dampened by isotropic noise. Here

$$|GHZ_n\rangle = \frac{1}{\sqrt{2}}(|00\cdots0\rangle + |11\cdots1\rangle)$$

and

$$|W_n\rangle = \frac{1}{\sqrt{n}}(|0\cdots01\rangle + |0\cdots10\rangle + \cdots + |1\cdots00\rangle)$$

are the $n$-qubit GHZ state and W state, respectively.

In this section, we illustrate our main result with some explicit examples. It should be pointed out that our criteria are suitable for any $n$-partite states. For simplicity, we give the following examples to show the detecting ability of our criteria.

<table>
<thead>

</table>

then \(\rho^{(G-W_n)}\) is \(k\)-nonseparable. Here the sum runs over all possible partitions \(\Upsilon = \Upsilon_1|\Upsilon_2|\cdots|\Upsilon_k\) of the considered system into \(k\) subsystems, \(\Phi_{\Upsilon_i}^T\) is an \(n\)-qubit state in which all the subsystems contained in the \(i\)-th subset of the partition \(\Upsilon\) are in the state \(|1\rangle\) while others are in the state \(|0\rangle\), and \(|\Phi_{\Upsilon_i}^T\rangle\) is an \(n\)-qubit state in which the \(l\)-th qubit is in the state \(|0\rangle\) for each \(l \in \Upsilon_i\) while others are in the state \(|1\rangle\).

Let \(|\Phi\rangle = |\Phi_1\rangle|\Phi_2\rangle = |0\rangle^\otimes n|1\rangle^\otimes n\). By inequality (\(\ast\)) of Ref. [31], one can derive that if

$$\frac{\alpha}{2} > \sum_{\{\Upsilon\}} \prod_{i=1}^{k} \left( \beta(\Phi_{\Upsilon_i}^T|W_n\rangle\langle W_n|\Phi_{\Upsilon_i}^T) + \frac{1 - \alpha - \beta}{2^n} \right)^\frac{1}{2},$$

then \(\rho^{(G-W_n)}\) is not \(k\)-separable. Here the sum runs over all possible partitions \(\Upsilon = \Upsilon_1|\Upsilon_2|\cdots|\Upsilon_k\) of the considered system into \(k\) subsystems, \(\Phi_{\Upsilon_i}^T\) is an \(n\)-qubit state in which all the subsystems contained in the \(i\)-th subset of the partition \(\Upsilon\) are in the state \(|1\rangle\) while others are in the state \(|0\rangle\), and \(|\Phi_{\Upsilon_i}^T\rangle\) is an \(n\)-qubit state in which the \(l\)-th qubit is in the state \(|0\rangle\) for each \(l \in \Upsilon_i\) while others are in the state \(|1\rangle\).

Let \(|\Phi\rangle = |\Phi_1\rangle|\Phi_2\rangle = (\frac{|0\rangle+|1\rangle}{\sqrt{2}})^\otimes n(\frac{|0\rangle-|1\rangle}{\sqrt{2}})^\otimes n\). By inequality (\(\ast\)) of Ref. [31], one can obtain that if

$$n\beta > \sum_{\{\Upsilon\}} \prod_{i=1}^{k} \left( \frac{(1+n|\Upsilon_i|)^2\alpha}{2} + \frac{(n-2|\Upsilon_i|)^2\beta}{n} + 1 - \alpha - \beta \right)^\frac{1}{2},$$

then \(\rho^{(G-W_n)}\) is \(k\)-nonseparable. Here the sum runs over all possible partitions \(\Upsilon = \Upsilon_1|\Upsilon_2|\cdots|\Upsilon_k\) of the considered system into \(k\) subsystems, and \(|\Upsilon_i|\) is the number of elements in the set \(\Upsilon_i\).
Here the different classes of multipartite entanglement given by our inequality (3) are shown for the state $\rho^{(G-W_n)} = \alpha|\text{GHZ}_n\rangle\langle\text{GHZ}_n| + \beta|W_n\rangle\langle W_n| + \frac{1}{2^n}\mathbb{I}$, $n = 4, k = 3$. The lines I (red line) and i (red line) represent the thresholds of the detection for 3-nonseparable states identified by inequality (3) in Theorem 1 in the computational basis and $45^\circ$ basis, respectively. The lines (i) (blue line) and (ii) (blue line) represent the thresholds of the detection for 3-nonseparable states identified by the inequality (3) in Ref. [31] in the computational basis. There is no 3-nonseparable states identified by the inequality (3) in Ref. [31] in the $45^\circ$ basis. The states in the region above the line I identify entanglement ($k = 3$) detected by inequality (3) in Theorem 1. The area encircled by the curve I, the $\beta$ axis, the line (i), the line $\alpha + \beta = 1$, and the line (ii) contains 3-nonseparable states detected only by our inequality (3) in Theorem 1.

For the family $\rho^{(G-W_n)}$, our criteria can detect multipartite entanglement ($k$-nonseparable states) that had not been identified so far.

The detection parameter spaces of our $k$-separability criteria (inequality (3) ) and that in Ref. [31] for $n = 4, k = 3$ are illustrated in Fig.1.

The detection parameter spaces of our $k$-separability criteria (inequality (3) ) for $n = 5$ are illustrated in Fig.2. Here the different classes of multipartite entanglement given by our inequality (3) are shown for $\rho^{(G-W_n)}$.

**Example 2** Consider the $n$-qubit state, W state mixed with white noise,

$$\rho^{(W_n)}(\beta) = \beta|W_n\rangle\langle W_n| + \frac{1-\beta}{2^n}\mathbb{I}. \tag{21}$$

By our Theorem, one can derive that if

$$1 \geq \beta > \frac{n(2n-k-1)}{2^n(k-1) + n(2n-k-1)}, \tag{22}$$

then $\rho^{(W_n)}(\beta)$ is not $k$-separable. In the case $k = 2$, inequality (3) detects W state mixed with white noise, $\rho^{(W_n)}(\beta)$, for $1 \geq \beta > \frac{n(2n-3)}{2^n(n-3)+2^n}$ as genuinely $n$-partite entangled, whereas inequality (II) of Ref. [30] detects it for $1 \geq \beta > \frac{n^2(n-2)+2^n}{n^2(n-2)+2^n}$.

**Example 3** Consider the $n$-qubit state family given by a mixture of the identity matrix, the W state and the anti-W state

$$\rho^{(W-W_n)} = \frac{1-a-b}{2^n}I_{2^n} + a|W_n\rangle\langle W_n| + b|\tilde{W}_n\rangle\langle \tilde{W}_n|, \tag{23}$$

where $|W_n\rangle = \frac{1}{\sqrt{n}}(|00\cdots00\rangle + |00\cdots01\rangle + \cdots + |10\cdots00\rangle)$ and $|\tilde{W}_n\rangle = \frac{1}{\sqrt{n}}(|11\cdots10\rangle + |11\cdots10\rangle + \cdots + |01\cdots11\rangle)$. For this family, our criteria can detect $k$-nonseparable states which have previously not been identified.

Let $|\Phi\rangle \in \{|0\rangle^n\otimes|0\rangle^n, |1\rangle^n\otimes|1\rangle^n, |0\rangle^n\otimes|1\rangle^n, |1\rangle^n\otimes|0\rangle^n, \frac{1}{\sqrt{2}}(|0\rangle \otimes |0\rangle) \otimes n, \frac{1}{\sqrt{2}}(|0\rangle \otimes |1\rangle) \otimes n, \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) \otimes n, \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) \otimes n\}$. When $n \geq 4$, inequality (3) in Ref. [31] cannot detect genuine $n$-partite entanglement for the family $\rho^{(W-W_n)}$. It cannot detect both 3-nonseparable and 4-nonseparable states for the family $\rho^{(W-W_n)}$.

Figure 3 illustrates the entanglement area detected by our inequality (3), inequality (3) in Ref. [31] and Proposition 2 in Ref. [29] for $\rho^{(W-W_n)}$, respectively. The area detected by our inequality (3) is the largest.
I, II, III and IV: Computational Basis  
i, ii, iii and iv: 45° Basis  
I and i: k=2  
II and ii: k=3  
III and iii: k=4  
IV and iv: k=5  

FIG. 2: (Color online). Here the detection quality of the inequality (3) in Theorem 1 is shown for the state $\rho^{(G-W_n)} = \alpha |GHZ_n\rangle \langle GHZ_n| + \beta |W_n\rangle \langle W_n| + \frac{1-\alpha -\beta}{2} I_n$, $n = 5$. The lines I (red line), II (green line), III (blue line) and IV (pink) represent the thresholds of the detection for genuine 5-partite entanglement ($k = 2$), entanglement ($k = 3$), entanglement ($k = 4$) and entanglement ($k = 5$) identified by the inequality (3) in Theorem 1 in the computational basis, respectively. The lines i (red line), ii (green line), iii (blue line) and iv (pink) represent the same identified by the inequality (3) in Theorem 1 in the 45° basis. The states in the area encircled by the curve I, the $\beta$ axis, the line $\alpha + \beta = 1$, the $\alpha$ axis and the curve i are genuine 5-partite entanglement; the states in the area encircled by the curve II, the $\beta$ axis, the line $\alpha + \beta = 1$, the $\alpha$ axis, and the curve ii are 3-nonseparable; the states in the area encircled by the curve III, the $\beta$ axis, the line $\alpha + \beta = 1$, the $\alpha$ axis, and the curve iii are 4-nonseparable; the states in the area encircled by the curve IV, the $\beta$ axis, the line $\alpha + \beta = 1$, the $\alpha$ axis, and the curve iv are 5-nonseparable.

FIG. 3: (Color online). Illustration of the detection with our inequality (3), inequality (*) in Ref.[31] and Proposition 2 in Ref.[29] for $\rho^{(W-\tilde{W}_3)} = \frac{1-a-b}{2} I_3 + a |W_3\rangle \langle W_3| + b |\tilde{W}_3\rangle \langle \tilde{W}_3|$. Here the red line I represents the threshold given by inequality (3) in Theorem 1 such that the region above it identifies 3-nonseparable (not fully separable) states. The region above the blue line II corresponds to entangled states (not fully separable) detected by Proposition 2 in Ref.[29]. The green lines i and ii represent the thresholds given by inequality (*) in Ref.[31] such that the area enclosed by the line ii (green), the $b$ axis, and line $a + b = 1$, and the area enclosed by the line i (green), line $a + b = 1$, and the $a$ axis are not 3-separable (3-nonseparable). So the area enclosed by the red line I, green line ii, blue line II, and green line i are not fully separable states detected only by our inequality (3) in Theorem 1.

The detection parameter spaces of our inequality (3) and inequality (*) in Ref.[31] for $\rho^{(W-\tilde{W}_4)}$ and $\rho^{(W-\tilde{W}_5)}$ are illustrated in Fig.4 and Fig.5, respectively. The space detected by the former is visibly larger. Let $|x_i\rangle = |0\rangle$ and $|\tilde{x}_i\rangle = |1\rangle$, by inequality (3) of our Theorem 1, if

$$(k - 1)a - \frac{n(2n-k-1)}{2^n}(1-a-b) > 0, \text{ when } n > 3,$$
FIG. 4: (Color online). The detection quality of our inequality \((3)\) in Theorem 1 and inequality \((*)\) in Ref.\[31\] is shown for the state \(\rho^{W-W_n} = \frac{1-a\cdot b}{n} |1_2\rangle + a |W_5\rangle + b |W_5\rangle |W_5\rangle, k = 3\). The red line I represents the threshold given by our inequality \((3)\) such that the region above it corresponds to 3-nonseparable states. The region above the green line i are not 3-separable states detected by inequality \((*)\) in Ref.\[31\]. The area enclosed by the red line I, the \(a\) axis, the green line i, and the \(b\) axis is the entanglement (3-nonseparable) detected only by our inequality \((3)\) in Theorem 1.

\[
(k - 1)a - \frac{3}{4} \sqrt{\frac{(1-a-b)(3-3a+5b)}{3}} - \frac{3(3-k)(1-a-b)}{2^n} > 0, \text{ when } n = 3, \tag{25}
\]

hold, then \(\rho^{W-W_n}\) is not \(k\)-separable. Similarly, let \(|x_i\rangle = |0\rangle\) and \(|\tilde{x}_i\rangle = |1\rangle\), by inequality (3) of our Theorem 1, if

\[
(k - 1)b - \frac{n(2n-k-1)(1-a-b)}{2^n} > 0, \text{ when } n > 3, \tag{26}
\]

\[
(k - 1)b - \frac{3}{4} \sqrt{\frac{(1-a-b)(3+5a-3b)}{3}} - \frac{3(3-k)(1-a-b)}{2^n} > 0, \text{ when } n = 3, \tag{27}
\]

hold, then \(\rho^{W_n-W_n}\) is not \(k\)-separable.

Using inequality \((*)\) in Ref.\[31\], let \(|\Phi\rangle = |\phi_1\rangle |\phi_2\rangle = \frac{|0\rangle + |1\rangle}{\sqrt{2}} \otimes \frac{|0\rangle - |1\rangle}{\sqrt{2}} \otimes \frac{|x\rangle}{\sqrt{n}}\), if

\[
\frac{n(a-b)}{2^n} > \sum_{i=1}^{k} \prod_{j=1}^{n}(\frac{(n-2)[U_j^i]^2(a+b)}{2^n} + \frac{1-a-b}{2^n})^\frac{1}{2}, \text{ when } n \text{ is odd}, \tag{28}
\]
\[
\frac{n(a+b)}{2^{a+b}} > \sum_{\mathcal{Y}} \prod_{i=1}^{k} \left( \frac{(n-2\mathcal{Y}_i)^2}{2^n} + \frac{1-a-b}{2^n} \right)^{\frac{k}{2}}, \quad \text{when } n \text{ is even},
\] (29)

hold, then \(\rho^{(W_n-W_n)}\) is not \(k\)-separable. Here the sum runs over all possible \(k\)-partitions \(\mathcal{Y} = \mathcal{Y}_1 \cdots \mathcal{Y}_k\), and \(|\mathcal{Y}_i|\) is the number of elements in the set \(\mathcal{Y}_i\).

Let \(\{A_i, i = 1, \ldots, 4\} = \{B_i, i = 1, \ldots, 4\} = \{C_i, i = 1, \ldots, 4\} = \{\frac{2}{\sqrt{2}}, \frac{c_2}{\sqrt{2}}, \frac{c_3}{\sqrt{2}}, \frac{c_4}{\sqrt{2}}\}\). One can directly derive from Proposition 2 in [29] that if \(\frac{1}{2} - \frac{5(a+b)}{6} - \frac{(a-b)^2}{9} < 0\), \(\rho^{(W-W_3)}\) is entangled (not fully separable).

V. EXPERIMENTAL IMPLEMENTATION

In this section, we show that our criteria can be easily implemented in experiment without quantum state tomography and then we give the local observables required to implement our criteria. A local observable is an observable such as \(L = B_1 \otimes B_2 \otimes \cdots \otimes B_n\) for short, where \(B_l\) denotes observable on subsystem \(l\), \(l = 1, 2, \ldots, n\). Thus, local observables can be measured locally.

Since a full quantum state tomography requires a huge number of measurements, it is important for separability criteria of multipartite systems to be experimentally implementable without such a procedure. Our criteria are experimentally accessible without quantum state tomography, due to the fact that it can be expressed in terms of density matrix elements, each of which can be measured with at most two observables. In fact, each term in the left hand side of inequality (3) can be determined by measuring two observables, while each term in the right hand side can be determined by a single observable. For any fixed \(\{\Phi_{ij}\}\), the number of density matrix elements in inequality (3) is \(n^2 + 1\), thus inequality (3) can be determined by measuring \(3(n^2-n) + n + 1\) observables. Compared to a huge number of measurements needed for quantum state tomography, which requires an exponentially increasing, the number of observables needed to determine inequality (3) not only grows significantly slower with \(n\), but more importantly has the great advantage of being independent of the dimension \(d_l\) of the subsystem \(l\), \(l = 1, 2, \ldots, n\).

The observables determining inequality (3) can be implemented by means of local observables. Next we describe the local observables required to implement our criteria in detail.

The observables associated with each term (diagonal matrix elements) of the right hand side in inequality (3) can be implemented by means of local observables, which can be seen from the following expressions
\[
\langle \phi_i | \rho | \phi_j \rangle = \sum_{\mathcal{Y}} \prod_{i=1}^{k} \frac{(n-2\mathcal{Y}_i)^2}{2^n} + \frac{1-a-b}{2^n},
\]
where \(\mathcal{Y} = \mathcal{Y}_1 \cdots \mathcal{Y}_k\), and \(|\mathcal{Y}_i|\) is the number of elements in the set \(\mathcal{Y}_i\). Thus, determining one diagonal matrix element requires only a single local observable.

From \(\sqrt{\langle \Phi_{ij} | \rho | \Phi_{ij} \rangle} = |\langle \phi_i | \rho | \phi_j \rangle|\), we should determine modulus of the off diagonal elements \(|\langle \phi_i | \rho | \phi_j \rangle|\) by measuring two observables \(O_{ij}\) and \(\tilde{O}_{ij}\), since \(\langle O_{ij} \rangle = 2\text{Re}(\langle \phi_i | \rho | \phi_j \rangle)\) and \(\langle \tilde{O}_{ij} \rangle = -2\text{Im}(\langle \phi_i | \rho | \phi_j \rangle)\). Here \(O_{ij} = |\phi_i \rangle \langle \phi_j | + |\phi_j \rangle \langle \phi_i |\) and \(\tilde{O}_{ij} = -i|\phi_i \rangle \langle \phi_j | + i|\phi_j \rangle \langle \phi_i |\). Without loss of generality, let \(i < j\). From
\[
O_{ij} = \frac{1}{2} T_1 \cdots T_{i-1} M T_{i+1} \cdots T_{j-1} M T_{j+1} \cdots T_n
+ \frac{1}{2} T_1 \cdots T_{i-1} M T_{i+1} \cdots T_{j-1} M T_{j+1} \cdots T_n,
\]
(30)
and
\[
\tilde{O}_{ij} = \frac{1}{2} T_1 \cdots T_{i-1} M T_{i+1} \cdots T_{j-1} M T_{j+1} \cdots T_n
- \frac{1}{2} T_1 \cdots T_{i-1} M T_{i+1} \cdots T_{j-1} M T_{j+1} \cdots T_n,
\]
(31)
where \(M_i = |\tilde{x}_i \rangle \langle x_i | + |x_i \rangle \langle \tilde{x}_i |\), \(\tilde{M}_i = i|x_i \rangle \langle \tilde{x}_i | - i\tilde{x}_i \rangle \langle x_i |\), one can determine the left hand side in inequality (3) by
\[
2(n^2 - n) \text{ local observables.}
\]
Therefore in total at most \(\frac{5(n^2-n)}{2} + n + 1\) local observables are needed to test our separability criteria inequality (3). For any unknown \(n\)-partite mixed states, experimental detection of entanglement (\(k\)-nonseparable) using our criteria require only \(\frac{5(n^2-n)}{2} + n + 1\) local measurements, which is much less than quantum state tomography that would require \((d_l^2 - 1)(d_l^2 - 1) \cdots (d_l^2 - 1)\) measurements. Thus, our \(k\)-separability criteria can be used for experimental detection of multipartite entanglement.

Of course, entanglement witness can be used for experimental detection of entanglement. It is enough to measure only one observable - entanglement witness - in order to detect entanglement in a given state. However, it can not easily be implemented in experiment if it is not decomposed into operators that can be measured locally. Therefore, for the experimental implementation it is necessary to decompose the witness into operators that can be measured locally. In section 6 of Ref. [27], Gühne and Tóth pointed out: To obtain a good local decomposition requires often some effort, especially proving that a given decomposition is optimal, is often very difficult. For any pure state there exists a witness that requires \(2n - 1\) measurements, but the robustness to noise may be small. Furthermore, there exist observables, for which the local decomposition requires \(\frac{2n(n-1)}{n+1}\) local measurements, which means that a local measurement of these observables requires nearly the same effort as state tomography.
VI. CONCLUSION

In this paper, we present practical $k$-separability criteria to identify $k$-nonseparable multipartite mixed states in arbitrary dimensional quantum systems. The resulting criteria are easily computable from the density matrix, and no optimization or eigenvalue computation is needed. Our criteria can be used to distinguish the different classes of multipartite entanglement and can detect many important multipartite entanglement states such as GHZ state, $W$ state, and anti $W$ state efficiently. They can be used for detecting not only genuine $n$-partite entangled mixed states ($k = 2$) but also $k$-nonseparable mixed multipartite states (not $k$-separable states) ($k = 3, 4, \cdots, n$). In addition, our criteria detect multipartite entanglement that had not been identified so far and can be used in today's experiments without the need for quantum state tomography.
